Recognizing Human Gait Signatures with GOTCHA

The Project

- 1. Extract consecutive frames from the videos
- 2. Use Open Pose to detect the skeleton of the subject in the frame
- 3. Store the coordinates of consecutive frame feature points in an array (information about the subject movement variations in time).
- 4. Create a NN that use as input the pattern array and give us the user id as output:
- 5. Use a lot of pattern array samples to train the network;
- 6. Try to reach the highest accuracy chosing the best loss function.
- 7. Classify if a user is indoor or outdoor

Libraries used

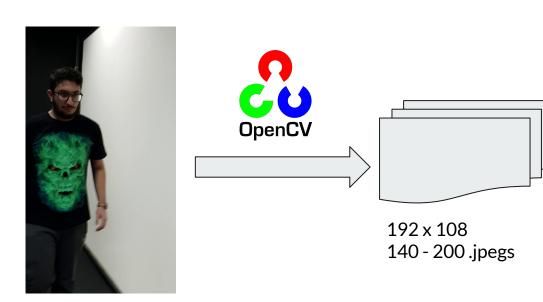

1) Extract consecutive frames from the videos

- only used folders 1 to 6 of the dataset
- started extracting after one third of the video
- resized and rotated all frames to reduce dimensions

1920x1080x60 .mp4

2) Use Open Pose to detect the skeleton of the subject in the frame

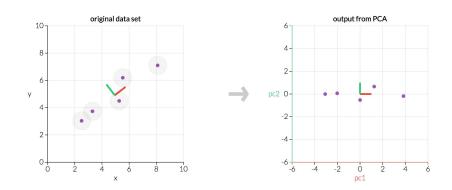

- OpenPose isn't robust to rotation
- A lot of joints missed, partly because of the way videos are shot (people in the BG, black t-Shirts in front of black BG)
- Extracted the XY coordinates of each joint over time
- Interpolation of missing data

3) Store the coordinates of consecutive frame feature points in an array (information about the subject movement variations in time).

	percent_missing
neckX	0.176255
neckY	0.176255
noseX	0.410344
noseY	0.410344
left_shoulderX	0.692628
	Supp
right_kneeX	55.524497
right_ankleY	79.546143
right_ankleX	79.546143
left_ankleX	81.109030
left_ankleY	81.109030

- removing columns with too much missing data as well as ears and eyes
- defined additional features like the vertical differences between both shoulders, hips and elbows.
- Scaled everything with Scikit StandardScaler

$$\mathbf{f} = [\mathbf{j}_1, \mathbf{j}_2, \mathbf{j}_3, \mathbf{j}_4, \mathbf{j}_5, \mathbf{j}_6, \mathbf{j}_7, \mathbf{j}_8, \mathbf{j}_9, \mathbf{j}_{10}, \mathbf{j}_{11}]$$
 (1)

$$\mathbf{j_i} = \frac{J_i}{s} + T, \qquad 1 \le i \le 11$$
 (2)

$$s = \frac{\|J_4 - J_2\|}{h}$$
(3)

- Performed PCA to reduce redundant information
- Separated the Dataframe in packages of 20 consecutive frames for each video.
- normalized all coordinates for scale by making the hip the pivot and scaling all samples according to one reference scale which is the distance from hip to neck.

End

Start

4) Create a NN that can predict the users ID from the Gait Pattern Array

LSTM - 512

CuDNNLSTM supported by nvidia optimization for parallel computation is 15 times faster than the default keras LSTM.

Stochastic Gradient Descent Optimizer with a learning-rate of 1e-4, decay towards 1e-6, momentum of 0.9 and nesterov.

LSTM - 256

Dense Layer 256

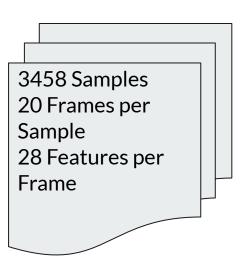

Dense Layer 128

Dense Layer 62

5) Use a lot of pattern array samples to train the network;

Balanced class weights labels due to uneven number of samples for all classes

Trained with 600 Epochs and a batch size of 16

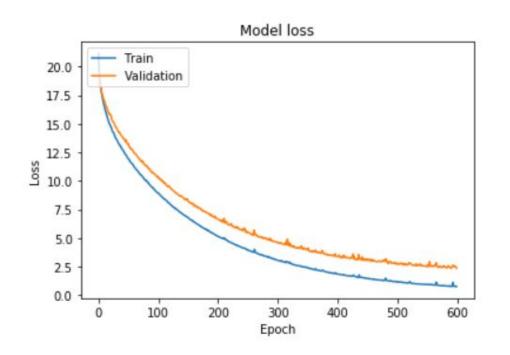

6) Try to reach the highest accuracy chosing the best loss function

precision

recall f1-score

support

The Network achieved on average 66% weighted accuracy.

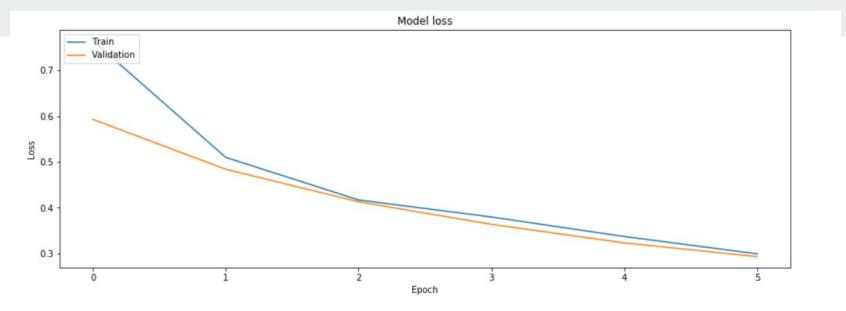

The highest peak in accuracy achieved was 72.59%

7) Classify if a user is indoor or outdoor

- 1) Extracted one frame from every video
- 2) Calculate a distribution histogram of brightness values (color if necessary)
- 3) Train a small network consisting of 2 Dense Layers with 3 and 4 neurons.

98.64% Accuracy after only 6 epochs, also works when shown a completely new frame from the same dataset.

Thank you
